# Camber LUE — Sandbox Load Test Results

*September 30, 2026 | camber-sandbox environment*

Karus gave the go-ahead to load test the sandbox environment. We ran 500 synthetic loan applications over 60 minutes (~8.3/min, a steady rate) through the full production path — WAF, API Gateway/mTLS, Lambda authorizer, Coordinator, Step Functions, Normalize, Karus Caller, and RSP Builder — the same path every real loan originator uses.

## Result: Pass

**All 500 applications completed successfully with zero errors.**

| Metric | Result |
|---|---|
| **Applications submitted** | 500 |
| **Applications resolved** | 500 (100%) |
| **Timeouts** | 0 |
| **Submission errors** | 0 |
| **Unexpected/system errors** | 0 |
| **Average response time** | 5.2 seconds |
| **95th percentile response time** | 6.0 seconds |
| **99th percentile response time** | 9.6 seconds |
| **Target response time** | ≤ 30 seconds |

## What this confirms

- The platform handled a full hour of steady, realistic traffic without any failures, timeouts, or slowdowns.
- Response times stayed well under target (avg ~5 seconds vs. a 30-second bar) throughout the entire run, including under sustained load.
- No infrastructure warning signs — no rate-limiting, no database pressure, no service errors — were observed at any point.

## Notes

- All test applications were synthetic/disposable and flagged as test traffic, so they were excluded from normal reporting and did not affect real data.
- 498 of 500 applications were declined by the underwriting engine (expected, since test applicant data isn't designed to qualify for approval) — this test measured system performance and reliability, not underwriting accuracy.
